

5.3 非光滑问题下的梯度方法

Def 5.4 Lipschitz连续函数, 称一个函数 Lipschitz, 就是

$$\|F(\eta) - F(0)\| \leq B \|\eta - 0\|,$$

对于可微函数, B-Lipschitz 等价于导数范数有界

中值定理 $\|F(\eta) - F(0)\| = \|F'(\xi)^T (\eta - 0)\| \leq \|F'(\xi)\| \cdot \|\eta - 0\|$

反之, 如果有 $\|F'(0)\| > B$, 那么由连续性, $\exists B(0, \delta)$, $\forall \eta, \xi \in B(0, \delta)$ $\|F'(\xi)\| > B$

$$\|F(\eta) - F(0)\| \leq B \|\eta - 0\|$$

可微情景, 构造次梯度

$$F(y) \geq F(x) + z^T (y - x), \text{ 称 } z \text{ 为 } F(x) \text{ 的一个次梯度}$$

若 F 凸且可微, 那么 $\partial F(x) = \{F'(x)\}$, 证明即

$$F(y) \geq F(x) + F'(x)^T (y - x) \quad (\text{凸可微函数有定义}) \quad \forall y \in \mathcal{X}$$

$$\frac{F(x+tv) - F(x)}{t} \leq F(x+tv) \leq tF(y) + (1-t)F(x)$$

$$F(y) - F(x) \geq \frac{F(x+tv) - F(x)}{t}$$

$$F(y) - F(x) \geq F'(x)^T (y - x)$$

反之,若 g 为一个次梯度

$$F(x+tv) - F(x) \geq t \langle g, v \rangle \xrightarrow{t \rightarrow 0} \langle F'(x), v \rangle \geq \langle g, v \rangle$$

$$\text{令 } v = -v \quad \langle F(x), -v \rangle \geq \langle g, -v \rangle \quad \langle F'(x), v \rangle \leq \langle g, v \rangle$$

$$F' = g$$

$$\theta \rightarrow 101 \quad \begin{cases} [-1, 1] & 101 \\ -1 & \end{cases}$$

$$\theta \rightarrow (1 - y\theta^T x)_+$$

$$\text{当 } y \neq 1 \quad 1 - y\theta^T x > 0 \quad \partial(1 - y\theta^T x) = \{-yX\}$$

$$1 - y\theta^T x \leq 0 \quad \partial f(\theta) = \{0\}$$

$$1 - y\theta^T x = 0 \quad \partial f(\theta) = \{-2yX\}$$

$$\frac{f(\theta) - f(\theta_0)}{\|\theta - \theta_0\|} \geq \langle g, \theta - \theta_0 \rangle$$

$$\langle -yX, \theta - \theta_0 \rangle \geq \langle g, \theta - \theta_0 \rangle$$

$$g = \{-k y X \mid k \in [2, 1]\} \quad k$$

$$h(u) = \max(0, u) \quad \partial h(u) = \begin{cases} \{1\}, & u > 0 \\ [0, 1], & u = 0 \\ \{0\}, & u < 0 \end{cases}$$

$$\text{那么 } \partial(1 - y\theta^T x)_+ = \begin{cases} \{-yX\} & y\theta^T x < 1 \\ \{-2yX\} & y\theta^T x = 1 \\ \{0\} & y\theta^T x > 1 \end{cases}$$

次梯度方法的收敛性:

F is convex, B -Lipschitz 连续 (某种意义上“等数有界”), $\|\eta_0 - \theta_0\|_2 \leq 1$

$\gamma_t = \frac{D}{\sqrt{t}}$, 学习率按 $\frac{1}{\sqrt{t}}$ 速度衰减, 使用次梯度来下降

证明, 与 SGD 类似 $\theta_t = \theta_{t-1} - \gamma_t g_t$, g_t 是一个次梯度

$$\|\theta_t - \eta_*\|_2^2 = \|\theta_{t-1} - \gamma_t g_t - \eta_*\|_2^2 \geq \|\theta_{t-1} - \eta_*\|_2^2 - 2\gamma_t \langle g_t, \theta_{t-1} - \eta_* \rangle + \gamma_t^2 \|g_t\|_2^2$$

$$+ \langle g_t, \theta_{t-1} - \eta_* \rangle \geq F(\theta_t) - F(\eta_*)$$

$$F(\eta_*) - F(\theta_{t-1}) \geq \langle g_t, \theta_{t-1} - \eta_* \rangle$$

$$2\gamma_t (F(\eta_*) - F(\theta_{t-1})) \leq \|\theta_{t-1} - \eta_*\|_2^2 - \|\theta_t - \eta_*\|_2^2 + \gamma_t^2 \|g_t\|_2^2$$

$$\sum_{s=1}^T \gamma_s (F(\eta_*) - F(\theta_{s-1})) \leq \|\theta_0 - \eta_*\|_2^2 - \|\theta_T - \eta_*\|_2^2 + \sum_{s=1}^T \gamma_s^2 \|g_s\|_2^2$$

$$F(\theta_s) \leq F$$

$$\min_{0 \leq s \leq T-1} |F(\theta_{s+1}) - F(\eta_*)| \leq \left(\frac{\|\theta_0 - \eta_*\|_2^2}{\sum_{s=1}^T \gamma_s} + \frac{\sum_{s=1}^T \gamma_s^2 B^2}{\sum_{s=1}^T \gamma_s} \right) = \frac{D^2}{2 \sum_{s=1}^T \gamma_s} + \frac{\sum_{s=1}^T \gamma_s^2}{2 \sum_{s=1}^T \gamma_s} B^2$$

$$\sum_{s=1}^T \gamma_s \geq \frac{D}{\sqrt{B}} \sqrt{T} \quad \sum \gamma_s^2 \leq \frac{D^2}{B^2} \sum \frac{1}{s} \leq \frac{D^2}{B^2} (1 + \log t)$$

$$\text{误差} \leq \frac{BD}{2\sqrt{t}} + \frac{BD(1+\log t)}{2\sqrt{t}}$$

Ex 5.20

如果 $\theta_t = \theta_{t-1} - \frac{\gamma'_t}{\|F'(\theta_{t-1})\|_2} F'(\theta_{t-1})$, $\gamma'_t = \frac{D}{\sqrt{t}}$, 这样我们不需要已知 B , 只用知道有界即可

结论是, 依然可以按 $\frac{BD(2+\log t)}{2\sqrt{t}}$ 控制, 记 $F'(\theta_{t-1}) = g_{t-1}$

$$\|\theta_t - \eta_*\|_2^2 = \|\theta_{t-1} - \eta_*\|_2^2 - 2\gamma'_t \langle g_{t-1}, \theta_{t-1} - \eta_* \rangle + (\gamma'_t)^2 \frac{1}{\|g_{t-1}\|^2} \|g_{t-1}\|^2$$

$$2\gamma'_t (F(\theta_t) - F(\eta_*)) \leq \|g_{t-1}\|_2 [\|\theta_{t-1} - \eta_*\|_2^2 - \|\theta_t - \eta_*\|_2^2 + (\gamma'_t)^2] \leq B(\|\theta_{t-1}\|_2 - \|\theta_t\|_2)$$

$$\sum_{s=1}^T \frac{D}{\sqrt{s}} 2 \min_{0 \leq s \leq T-1} |F(\theta_s) - F(\eta_*)| \leq BD^2 \left(1 + \sum_{s=1}^T \frac{1}{s}\right) \leq BD^2 (2 + \log t) + \frac{D^2}{t}$$

$$2D\sqrt{t} \min_{0 \leq s \leq T-1} |F(\theta_s) - F(\eta_*)| \leq BD^2 (2 + \log t)$$

Ex5.2 | 考虑一个凸集 $K \subset \mathbb{R}^n$, 并构造一个投影算子 Π_K

$\Pi_K(\eta) = \arg \min_{\eta \in K} \|\eta - \eta\|_2^2$, 说明投影算子是一个压缩映射, 即 $\|\Pi_K(\eta) - \Pi_K(\zeta)\|_2 \leq \|\eta - \zeta\|_2$

$\theta_t = \Pi_K(\theta_{t-1} - \gamma_t F(\theta_{t-1}))$, η_n 为 f 在 K 上的最小值,

按这种迭代法, $\min_{0 \leq s \leq t} F(\theta_s) - F(\eta_1) \leq DB \frac{2t \log t}{2 + \epsilon}$

$$\|\theta_t - \eta_1\| = \|\Pi_K(\theta_t) - \Pi_K(\eta_1)\|$$

投影 Π_K $p = \Pi_K(x)$ $p \in \{tz + (1-t)p \mid t \in [0,1], z \in K\}$

$$p_t = tz + (1-t)p \quad \varphi(t) = \|p_t - x\|_2^2$$

由于 $t=0$ 为 $\varphi(t)$ 最小值, $\varphi(t) = \|p - x + t(z - p)\|_2^2 = \|p - x\|_2^2$

$$\varphi'(0) = \langle p - x, z - p \rangle \geq 0 \quad \langle x - p, z - p \rangle \leq 0$$

同理 $q = \Pi_K(y)$, 满足 $\langle y - q, z - q \rangle \leq 0 \quad \forall z \in K$

$$\langle x - p, q - p \rangle \leq 0$$

$$\langle y - q, p - q \rangle \leq 0$$

$$\langle x - y - (p - q), q - p \rangle \leq 0 \quad \langle x - y, p - q \rangle \geq \langle p - q, p - q \rangle$$

$$\|p - q\| \|x - y\| \geq \|p - q\|^2 \quad \|p - q\| \leq \|x - y\|$$

接下来, 证明投影情况下依然满足收敛性

$$\|\theta_t - \eta_1\| \leq \|\Pi_K(\theta_{t-1} - \gamma_t F(\theta_{t-1})) - \Pi_K(\eta_1)\| \leq \|\theta_{t-1} - \gamma_t F(\theta_{t-1}) - \eta_1\|$$

接下来证明过程与次梯度证明方法相似

形式完全一致
